

How It Works: A Spin-Regulated Feedback Loop

$$P_{\text{ext}} = P_{\text{eq}} + P_{\text{BZ}} + P_{\text{res}}$$

Total extracted power is the sum of equatorial, BZ, and residual power.

$$f_{\text{eq}} + f_{\text{BZ}} + f_{\text{res}} = 1$$

The fractional contributions sum to unity.

This mechanism acts as a 'spin-extraction channel' that taps into the black hole's rotational energy to power the disk's luminosity, creating a self-sustaining and self-limiting cycle.

1. High Accretion
Gas flows in at super-Eddington rates.

2. Penrose Excitation
At the ISCO-ergoregion boundary, disk energy taps into BH spin energy.

3. Sustained $L/L_{\text{Edd}} > 1$
The extracted spin energy powers the disk, sustaining super-Eddington luminosity.

4. Spin Regulation (Feedback)
This energy extraction creates a counter-torque, slowing the black hole and enforcing a "spin ceiling," which in turn regulates the excitation process.
